Title : D etermination of $O$ ptimum H arvesting Regime in a Latanye Plantation.

## Authors: D onatian Gustave, Brent C harles and M argaret Severin

## Antecedents:

C entral to the Latanye Broom Industry is to have a sustainable harvesting system of the leaves. Preliminary observations using a sample of 28 plants on a farmer's holdings at La Pointe M on Repos (Paulina Ferdinand), indicated that leaves can be sustainably harvested. That plantation was established in 2001, and the first harvest was on 18 M arch 182004. The second harvest was in June 2004, three months later. The farmer used a $40 \%$ harvest of the leaves.

C onsequently, an experiment was designed to test the hypothesis that: Latanye leaves can be sustainably harvested every three months.

## Objective

To determine the optimum harvesting regimes for Latanye at M ary Aurilien's holding at Dennery.

## Methodology:

The Latanye Plantation was established in 2001, and was used as a research plot to test establishment of a Latanye plantation. The experimental design- random complete block was used to establish the plotsto capture the variability of the land in terms of aspect, slope and fertility based on the soil profile. The design and dimensions of the plot are illustrated figure \# 1 below.

Figure \# 1: Design of Research Plot.

Block one (1) and three (3) are on opposites sides of a slope and Block two (2) is at the top of a plateau. In addition plot one has greater shading caused by the presence of approximately $40 \%$ shading of larger trees.

For the first harvest done on September 29 2004, the number of leaves present initially and the number of leaves harvested were recorded. For the second harvest done on the January 31 2005, the same data was recorded.

In data analysis, the treatments and blocks were used as independent variables and the dependent variable was the difference between the number of leaves present in September 292004 and that present on January 312005 (No. of Leaves present September - N o. of Leaves present in January 2005). A nalysis was also done of interaction between the blocks and treatments. (Table: \#7).

The statistical programs used were: SPSS version 10.1, M icrosoft Office Excel 2003 and Statistica-release 5.0. A nalyses were done of H omogeneity of variance, analysis of variance (ANOVA), and Student-Newman-Keuls (S.N.K.) and Duncan tests to find out the difference and significance of the findings.

## Results

Presented in table \# 6 of the appendix, are the results of the number of leaves present in September 2004 and January 31 2005. Figure \#2 shows a general distribution of the number of leaves present for the two mentioned periods.

Figure \#2: Number of Leaves present Initially for September 2004 to January 2005

A nalysis of homogeneity of variance showed that the variances were equal for all groups in both cases of the treatment and the blocks to permit the application of ANOVA, as all values had a significance greater than 0.05 . The results are below in table \# 1 and 2 .

Table \# 1: Test of H omogeneity of V ariances for Treatments

| Levene <br> Statistic | df1 | df2 | Sig. |
| :---: | :---: | :---: | :---: |
| .531 | $\mathbf{3}$ | $\mathbf{8 7}$ | $\mathbf{. 6 6 2}$ |

Table \#2: Test of H omogeneity of V ariances for Blocks

| Levene <br> Statistic | df1 | df2 | Sig. |
| :--- | :---: | :---: | :---: |
| $\mathbf{1 . 9 3 5}$ | $\mathbf{2}$ | $\mathbf{8 8}$ | $\mathbf{. 1 5 0}$ |

Using treatment and block as independent variables, the analysis of variance (ANOVA) showed that there are significant differences in the number of leaves present from harvesting for the period. A significance of 0.00 was obtained for the Blocks and 0.04 for the treatments. The results are shown below in table \#3 and 4.

Table \#3: Test of AN OVA for Treatments

|  | Sum of <br> Squares | df | Mean <br> Square | F | Sig. |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Between <br> G roups | 53.564 | 3 | 17.855 | 4.732 | .004 |
| Within <br> G roups | 328.260 | 87 | 3.773 |  |  |
| Total | 381.824 | 90 |  |  |  |

Table \#4: Test of AN OVA for Blocks

|  | Sum of <br> Squares | df | M ean <br> Square | F | Sig. |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Between <br> Groups | 69.485 | 2 | 34.743 | 9.789 | .000 |
| W ithin <br> Groups | 312.339 | 88 | 3.549 |  |  |
| Total | 381.824 | 90 |  |  |  |

U sing the S.N.K. test, the treatments $30 \%, 40 \%$ and $50 \%$ form a homogenous group (table \#5). At the Latanye plantation studied, this observation was confirmed using Table \#6, in which $62 \%$ (16) and $50 \%(11) 32 \%$ (8) of the plants had in January 2005-an equal number of leaves or one ( $1+/$ ) leaf more or less than the quantity of leaves present in September 2004 for the respective treatments

Also noted in table \#5 is that the $40 \%, 50 \%$ and $60 \%$ treatments also form another homogenous group. Again for the respective treatments at Mary Aurilien's farm this was observed using Table \#6, in which $37 \%$ (8), $64 \%$ (16), and $89 \%$ (16) of the plants had in January two or more leaves re-grown January 2005.

O ne may note the disparity between the number of leaves present initially for the $30 \%$ and the $60 \%$ treatments, and the similarity in the leaves present initially that of the 40 and $50 \%$ treatment. Figure \#3 is a graphic representation of the disparity and similarities in the average difference of Latanye leaves present in January 2005.

Table \#5: $\quad$ Results of Student-N ewman-Keuls for Treatments.

|  | N | Subset for <br> alpha=.05 |  |
| :---: | :---: | :---: | :---: |
| TREATM ENT |  | 1 | 2 |

| $40 \%$ | 22 | 2.0000 | 2.0000 |
| $50 \%$ | 25 | 2.3600 | 2.3600 |
| $60 \%$ | 18 |  | 3.1667 |
| Sig. |  | .056 | .117 |

Figure \#3: Variation of the mean of the differences of number of leaves for Treatments

TREATMEN

There is also a significant difference between Block one and two (Block 1 and 2), and Block three (Block 3) in terms of the leaves re-grown in January 2005. Table \#6 presents the results in the field: for Block 3 all trees measured in January had an equal number or more leaves present initially than in September 2004. This was irrespective of the treatment applied. Block one and two (1 and 2) had values of number of leaves harvested oscillating more and less than initial number of leaves present in September 2004.

Also observed is interaction between the Blocks and treatments: for block1 and 30\% treatment, Block 2 and 50 and $60 \%$ treatments and Block 3 with the $50 \%$ treatment. (Table\# 7)

## Discussion and Conclusion:

The interaction in Block one may be caused by the shading of larger trees present. Block 1 is the most shaded plot, receiving the least amount of sunlight. W ith this assumption and mindful that there is no information of soil fertility in this study, one may infer that in shaded conditions that the $60 \%$ harvesting regime resulted in over harvesting of leaves, and the $30 \%$ regime resulted in the under harvesting of leaves in Block 1. This explanation is validated reviewing table \#6 in which for the $60 \%$ treatment, one may observe that none of the plants were able to recuperate to the initial number of kaves present in September 2004; for the $30 \%$ treatment the numbers of leaves present in January 2005 were on average the same or one ( $1+/-$ ) more or less than the initial number
of leaves present in September 2004. Consequently the $40 \%$ and $50 \%$ harvesting regimes appear most appropriate for Block 1 as they result in having two (2+l-) leaves on average, or the same number of leaves three months later.

Block 2 is flat and interaction was observed for the treatments $50 \%$ and $60 \%$. Block 2 is similar to Block 1 in terms of the $60 \%$ and $30 \%$ treatments. In Block 2, the 60 and $30 \%$ harvest regimes resulted in over-harvesting and under-harvesting respectively, but, in this case the $50 \%$ treatment also had the result that none of the plants were able to recuperate to the initial number of leaves present in September 2004. For these conditions in Block 2, the $40 \%$ treatment appears to be most appropriate for optimum harvesting.

Block 3 was the block with he highest productivity as it was the only block in which the plants were able to recuperate from the four treatments to obtain an equal number or more leaves in January 2005. Block 3 is sloping and has a greater exposure to sunlight. Block 3 appears to be more suited to the growth of Latan ye. There is interaction observed for $60 \%$ treatment and Block 3. Similar to Block land 2, the 30\% treatment resulted in under-harvesting, but unlike them, this all the plants in this block recuperated from harvesting regimes as high 40,50 and $60 \%$.

The results suggest that it is possible to sustainably harvest Latanye at Mary Aurilien's Latanye plantation with $40 \%$ to $50 \%$ removal of leaves for the mentioned periodSeptember to January. On average two ( $2+/$ ) leaves re- grew with the $40 \%$ and $50 \%$ treatment.

Latanye Farmers claim that a Latanye plant produces one leaf per month. This may serve as a plausible explanation for the regrowth of the leaves in Latanye. In table \#8 of the Appendix, three (3) leaves were added to the number of leaves left after harvesting in September 2004, and in Figure \#4 is a graphic representation of a comparison between the estimated number of leaves present and actual number of leaves present in January 2005.

Figure \#4: Comparison between the Estimated and Actual Number of leaves Regrown in January 2005

## Appendix
